Taxi demand prediction in New York City

Data Information

Ge the data from: http://www.nyc.gov/html/tlc/html/about/trip_record_data.shtml (2016 data) The data used in the attached datasets were collected and provided to the NYC Taxi and Limousine Commission (TLC)

Information on taxis:

Yellow Taxi: Yellow Medallion Taxicabs

These are the famous NYC yellow taxis that provide transportation exclusively through street-hails. The number of taxicabs is limited by a finite number of medallions issued by the TLC. You access this mode of transportation by standing in the street and hailing an available taxi with your hand. The pickups are not pre-arranged.

For Hire Vehicles (FHVs)

FHV transportation is accessed by a pre-arrangement with a dispatcher or limo company. These FHVs are not permitted to pick up passengers via street hails, as those rides are not considered pre-arranged.

Green Taxi: Street Hail Livery (SHL)

The SHL program will allow livery vehicle owners to license and outfit their vehicles with green borough taxi branding, meters, credit card machines, and ultimately the right to accept street hails in addition to pre-arranged rides.

Credits: Quora

Footnote:

In the given notebook we are considering only the yellow taxis for the time period between Jan - Mar 2015 & Jan - Mar 2016

Data Collection

Data has been collected for all yellow taxi trips data from jan-2015 to dec-2016(Will be using only 2015 data)

Features in the dataset:

Field Name	Descr	iption
	A code indicating the TPEP provider that provided the results to the TPEP provider that provided the TPEP pro	ologies
tpep_pickup_datetime	The date and time when the meter was eng	gaged.
tpep_dropoff_datetime	The date and time when the meter was diseng	gaged.
Passenger_count	The number of passengers in the vehicle. This is a driver-entered	value.
Trip_distance	The elapsed trip distance in miles reported by the taxi	meter.
Pickup_longitude	Longitude where the meter was eng	gaged.
Pickup_latitude	Latitude where the meter was eng	gaged.
RateCodeID	The final rate code in effect at the end of the Standar Standa	rd rate JFK lewark hester

	6. Group ride
Store_and_fwd_flag	This flag indicates whether the trip record was held in vehicle memory before sending to the vendor aka "store and forward," because the vehicle did not have a connection to the server. Y= store and forward trip N= not a store and forward trip
Dropoff_longitude	Longitude where the meter was disengaged.
Dropoff_latitude	Latitude where the meter was disengaged.
Payment_type	A numeric code signifying how the passenger paid for the trip. Credit card Cash No charge Dispute Unknown Voided trip
Fare_amount	The time-and-distance fare calculated by the meter.
Extra	thm:miscellaneous extras and surcharges. Currently, this only includes. the 0.50 and 1 rush hour and overnight charges.
MTA_tax	0.50 MTA tax that is automatically triggered based on the metered rate in use.
Improvement_surcharge	0.30 improvement surcharge assessed trips at the flag drop. the improvement surcharge began being levied in 2015.
Tip_amount	Tip amount – This field is automatically populated for credit card tips.Cash tips are not included.
Tolls_amount	Total amount of all tolls paid in trip.
Total_amount	The total amount charged to passengers. Does not include cash tips.

ML Problem Formulation

Time-series forecasting and Regression

- To find number of pickups, given location cordinates(latitude and longitude) and time, in the query reigion and surrounding regions.

To solve the above we would be using data collected in Jan - Mar 2015 to predict the pickups in Jan - Mar 2016.

Performance metrics

- 1. Mean Absolute percentage error.
- 2. Mean Squared error.

Data Cleaning

In this section we will be doing univariate analysis and removing outlier/illegitimate values which may be caused due to some error

In [10]:

#table below shows few datapoints along with all our features
month.head(5)

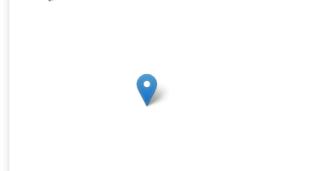

Out[10]:

	VendorID	tpep_pickup_datetime	tpep_dropoff_datetime	passenger_count	trip_distance	pickup_longitude	pickup_latitude	RateCode
0	2	2015-01-15 19:05:39	2015-01-15 19:23:42	1	1.59	-73.993896	40.750111	
1	1	2015-01-10 20:33:38	2015-01-10 20:53:28	1	3.30	-74.001648	40.724243

4								Þ

1. Pickup Latitude and Pickup Longitude

It is inferred from the source https://www.flickr.com/places/info/2459115 that New York is bounded by the location cordinates (lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with pickups which originate within New York.

```
In [11]:
# Plotting pickup cordinates which are outside the bounding box of New-York
# we will collect all the points outside the bounding box of newyork city to outlier locations
outlier locations = month[((month.pickup longitude <= -74.15) | (month.pickup latitude <= 40.5774)|
                   (month.pickup longitude >= -73.7004) | (month.pickup latitude >= 40.9176))]
# creating a map with the a base location
# read more about the folium here: http://folium.readthedocs.io/en/latest/quickstart.html
# note: you dont need to remember any of these, you dont need indeepth knowledge on these maps and
plots
map osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
# we will spot only first 100 outliers on the map, plotting all the outliers will take more time
sample locations = outlier locations.head(10000)
for i, j in sample locations.iterrows():
    if int(j['pickup latitude']) != 0:
        folium.Marker(list((j['pickup_latitude'],j['pickup_longitude']))).add_to(map_osm)
map osm
```

Observation:- As you can see above that there are some points just outside the boundary but there are a few that are in either South america, Mexico or Canada

2. Dropoff Latitude & Dropoff Longitude

It is inferred from the source https://www.flickr.com/places/info/2459115 that New York is bounded by the location cordinates (lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with dropoffs which are within New York.

```
In [12]:
```

```
# read more about the Iolium here: http://Iolium.readthedocs.lo/en/latest/quickstart.ntml
# note: you dont need to remember any of these, you dont need indeepth knowledge on these maps and
plots
map osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
# we will spot only first 100 outliers on the map, plotting all the outliers will take more time
sample locations = outlier locations.head(10000)
for i, j in sample_locations.iterrows():
    if int(j['pickup latitude']) != 0:
        folium.Marker(list((j['dropoff_latitude'],j['dropoff_longitude']))).add_to(map_osm)
map osm
```

Observation:- The observations here are similar to those obtained while analysing pickup latitude and longitude

3. Trip Durations:

According to NYC Taxi & Limousine Commision Regulations the maximum allowed trip duration in a 24 hour interval is 12 hours.

```
#The timestamps are converted to unix so as to get duration(trip-time) & speed also pickup-times i
n unix are used while binning

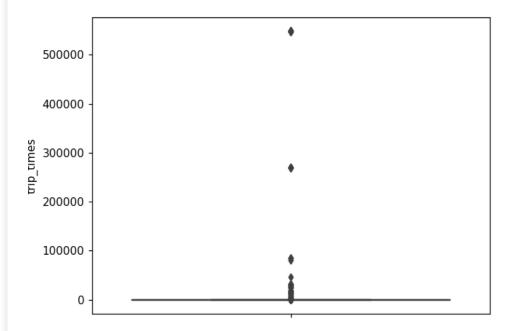

# in out data we have time in the formate "YYYY-MM-DD HH:MM:SS" we convert thiss sting to python t
ime formate and then into unix time stamp
# https://stackoverflow.com/a/27914405

def convert_to_unix(s):
    return time.mktime(datetime.datetime.strptime(s, "%Y-%m-%d %H:%M:%S").timetuple())

# we return a data frame which contains the columns
# 1.'passenger_count' : self explanatory
# 2.'trip_distance' : self explanatory
# 3.'pickup_longitude' : self explanatory
# 4.'pickup_latitude' : self explanatory
# 5.'dropoff_longitude' : self explanatory
# 5.'dropoff_longitude' : self explanatory
# 6.'dropoff_latitude' : self explanatory
# 7.'total_amount' : total fair that was paid
```

```
# 8.'trip times' : duration of each trip
# 9.'pickup_times : pickup time converted into unix time
# 10.'Speed' : velocity of each trip
def return with trip times(month):
   duration = month[['tpep_pickup_datetime','tpep_dropoff_datetime']].compute()
   #pickups and dropoffs to unix time
   duration pickup = [convert to unix(x) for x in duration['tpep pickup datetime'].values]
   duration_drop = [convert_to_unix(x) for x in duration['tpep_dropoff_datetime'].values]
    #calculate duration of trips
   durations = (np.array(duration_drop) - np.array(duration_pickup))/float(60)
   #append durations of trips and speed in miles/hr to a new dataframe
   new frame =
month[['passenger count','trip distance','pickup longitude','pickup latitude','dropoff longitude',
'dropoff latitude','total amount']].compute()
   new frame['trip times'] = durations
   new frame['pickup times'] = duration pickup
   new frame['Speed'] = 60*(new_frame['trip_distance']/new_frame['trip_times'])
   return new frame
# print(frame_with_durations.head())
# passenger_count trip_distance pickup_longitude pickup_latitude dropoff_longitude

Observation:- As even the 99.9th percentile value doesnt look like an outlier, as there is not much difference between the 99.8th percentile and 99.9th percentile, we move on to do graphical analyis

```
#below plot shows us the fare values(sorted) to find a sharp increase to remove those values as ou
tliers
# plot the fare amount excluding last two values in sorted data
plt.plot(var[:-2])
plt.show()
```

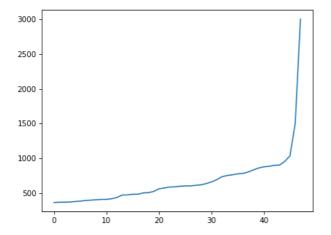

```
# a very sharp increase in fare values can be seen
# plotting last three total fare values, and we can observe there is share increase in the values
plt.plot(var[-3:])
plt.show()
```

In [0]:

```
#now looking at values not including the last two points we again find a drastic increase at aroun
d 1000 fare value
# we plot last 50 values excluding last two values
plt.plot(var[-50:-2])
plt.show()
```

Remove all outliers/erronous points.

```

Inference:

• The main objective was to find a optimal min. distance(Which roughly estimates to the radius of a cluster) between the clusters which we got was 40

In [0]:

```
# if check for the 50 clusters you can observe that there are two clusters with only 0.3 miles apa
rt from each other
# so we choose 40 clusters for solve the further problem

# Getting 40 clusters using the kmeans
kmeans = MiniBatchKMeans(n_clusters=40, batch_size=10000,random_state=0).fit(coords)
frame_with_durations_outliers_removed['pickup_cluster'] =
kmeans.predict(frame_with_durations_outliers_removed[['pickup_latitude', 'pickup_longitude']])
```

Plotting the cluster centers:

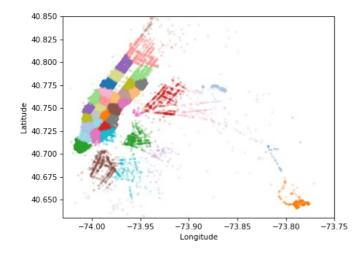

In [23]:

```
# Plotting the cluster centers on OSM
cluster_centers = kmeans.cluster_centers_
cluster_len = len(cluster_centers)
map_osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
for i in range(cluster_len):

```
# Ans: consider we have data of some month in 2015 jan 1st, 10 _ _ _ 20, i.e there are 10 pickups that are happened in 1st
# 10st 10min intravel, 0 pickups happened in 2nd 10mins intravel, 0 pickups happened in 3rd 10min intravel
# and 20 pickups happened in 4th 10min intravel.
# in fill_missing method we replace these values like 10, 0, 0, 20
# where as in smoothing method we replace these values as 6,6,6,6,6, if you can check the number of pickups
# that are happened in the first 40min are same in both cases, but if you can observe that we look ing at the future values
# wheen you are using smoothing we are looking at the future number of pickups which might cause a data leakage.

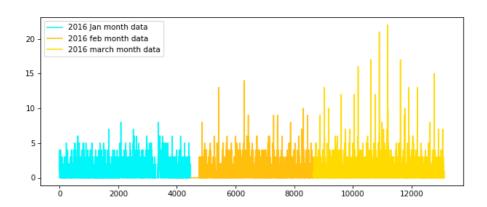

# so we use smoothing for jan 2015th data since it acts as our training data
# and we use simple fill_misssing method for 2016th data.

Modelling: Baseline Models

Now we get into modelling in order to forecast the pickup densities for the months of Jan, Feb and March of 2016 for which we are using multiple models with two variations

- 1. Using Ratios of the 2016 data to the 2015 data i.e $R_t = P_t^{2016}/P_t^{2015}$
- 2. Using Previous known values of the 2016 data itself to predict the future values

Simple Moving Averages

The First Model used is the Moving Averages Model which uses the previous n values in order to predict the next value

Using Ratio Values - $R_t = (R_{t-1} + R_{t-2} + R_{t-3} \dots R_{t-n})/n$

In [0]:

```
def MA R Predictions(ratios, month):
    predicted ratio=(ratios['Ratios'].values)[0]
    error=[]
    predicted values=[]
   window size=3
    predicted ratio values=[]
    for i in range(0,4464*40):
        if i%4464==0:
            predicted ratio values.append(0)
            predicted values.append(0)
            error.append(0)
            continue
        predicted ratio values.append(predicted ratio)
        predicted_values.append(int(((ratios['Given'].values)[i])*predicted_ratio))
        error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted ratio)-(ratios['Pred
iction'].values)[i],1))))
        if i+1>=window size:
           predicted ratio=sum((ratios['Ratios'].values)[(i+1)-window size:(i+1)])/window size
        else:
            predicted ratio=sum((ratios['Ratios'].values)[0:(i+1)])/(i+1)
    ratios['MA R Predicted'] = predicted values
    ratios['MA R Error'] = error
    mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].values)
alues))
   mse err = sum([e^{**2} for e in error])/len(error)
    return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 3 is optimal for getting the best results using Moving Averages using previous Ratio values therefore we get $R_t = (R_{t-1} + R_{t-2} + R_{t-3})/3$

Next we use the Moving averages of the 2016 values itself to predict the future value using $P_t = (P_{t-1} + P_{t-2} + P_{t-3} + \dots + P_{t-n})/n$

```
def MA P Predictions(ratios, month):
   predicted value=(ratios['Prediction'].values)[0]
   error=[]
   predicted values=[]
   window size=1
   predicted ratio values=[]
   for i in range(0,4464*40):
       predicted values.append(predicted value)
        error.append(abs((math.pow(predicted_value-(ratios['Prediction'].values)[i],1))))
       if i+1>=window size:
            predicted value=int(sum((ratios['Prediction'].values)[(i+1)-window size:
(i+1)])/window size)
            predicted value=int(sum((ratios['Prediction'].values)[0:(i+1)])/(i+1))
   ratios['MA P Predicted'] = predicted values
   ratios['MA_P_Error'] = error
   mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].v
```

```
alues))
   mse_err = sum([e**2 for e in error])/len(error)
   return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 1 is optimal for getting the best results using Moving Averages using previous 2016 values therefore we get $P_t = P_{t-1}$

Weighted Moving Averages

The Moving Avergaes Model used gave equal importance to all the values in the window used, but we know intuitively that the future is more likely to be similar to the latest values and less similar to the older values. Weighted Averages converts this analogy into a mathematical relationship giving the highest weight while computing the averages to the latest previous value and decreasing weights to the subsequent older ones

Weighted Moving Averages using Ratio Values - $R_t = (N*R_{t-1} + (N-1)*R_{t-2} + (N-2)*R_{t-3}....1*R_{t-n})/(N*(N+1)/2)$

In [0]:

```
def WA R Predictions(ratios, month):
    predicted ratio=(ratios['Ratios'].values)[0]
    alpha=0.5
    error=[]
    predicted values=[]
    window size=5
    predicted ratio values=[]
    for i in range(0,4464*40):
       if i%4464==0:
            predicted ratio values.append(0)
            predicted_values.append(0)
            error.append(0)
            continue
        predicted_ratio_values.append(predicted_ratio)
        predicted values.append(int(((ratios['Given'].values)[i])*predicted ratio))
        error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted_ratio)-(ratios['Predicted_ratio)
iction'].values)[i],1))))
        if i+1>=window_size:
            sum values=0
            sum of coeff=0
            for j in range(window size, 0, -1):
                sum_values += j*(ratios['Ratios'].values)[i-window_size+j]
                sum of coeff+=j
            predicted ratio=sum values/sum of coeff
        else:
            sum values=0
            sum of coeff=0
            for j in range(i+1,0,-1):
                sum_values += j*(ratios['Ratios'].values)[j-1]
                sum of coeff+=j
            predicted ratio=sum values/sum of coeff
    ratios['WA R Predicted'] = predicted values
    ratios['WA R Error'] = error
   mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].values)/
alues))
    mse err = sum([e^{**2} for e in error])/len(error)
    return ratios, mape err, mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 5 is optimal for getting the best results using Weighted Moving Averages using previous Ratio values therefore we get $R_t = (5*R_{t-1}+4*R_{t-2}+3*R_{t-3}+2*R_{t-4}+R_{t-5})/15$

Weighted Moving Averages using Previous 2016 Values - $P_t = (N*P_{t-1} + (N-1)*P_{t-2} + (N-2)*P_{t-3}....1*P_{t-n})/(N*(N+1)/2)$

```
In [0]:
```

```
def WA_P_Predictions(ratios,month):
    predicted_value=(ratios['Prediction'].values)[0]
    error=[]
    predicted_values=[]
```

```
window size=2
for i in range(0,4464*40):
    predicted_values.append(predicted_value)
    error.append(abs((math.pow(predicted value-(ratios['Prediction'].values)[i],1))))
    if i+1>=window size:
        sum values=0
        sum of coeff=0
        for j in range(window size, 0, -1):
            sum values += j*(ratios['Prediction'].values)[i-window size+j]
            sum_of_coeff+=j
        predicted value=int(sum values/sum of coeff)
        sum values=0
        sum of coeff=0
        for j in range (i+1,0,-1):
            sum values += j*(ratios['Prediction'].values)[j-1]
            sum of coeff+=j
        predicted value=int(sum values/sum of coeff)
ratios['WA P Predicted'] = predicted values
ratios['WA P_Error'] = error
mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].v
mse_err = sum([e**2 for e in error])/len(error)
return ratios, mape err, mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 2 is optimal for getting the best results using Weighted Moving Averages using previous 2016 values therefore we get $P_t = (2 * P_{t-1} + P_{t-2})/3$

Exponential Weighted Moving Averages

https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average Through weighted averaged we have satisfied the analogy of giving higher weights to the latest value and decreasing weights to the subsequent ones but we still do not know which is the correct weighting scheme as there are infinetly many possibilities in which we can assign weights in a non-increasing order and tune the hyperparameter window-size. To simplify this process we use Exponential Moving Averages which is a more logical way towards assigning weights and at the same time also using an optimal window-size.

In exponential moving averages we use a single hyperparameter alpha (a) which is a value between 0 & 1 and based on the value of the hyperparameter alpha the weights and the window sizes are configured.

For eg. If $\alpha=0.9$ then the number of days on which the value of the current iteration is based is~ $1/(1-\alpha)=10$ i.e. we consider values 10 days prior before we predict the value for the current iteration. Also the weights are assigned using 2/(N+1)=0.18, where N = number of prior values being considered, hence from this it is implied that the first or latest value is assigned a weight of 0.18 which keeps exponentially decreasing for the subsequent values.

```
R_{t}^{'} = \alpha * R_{t-1} + (1 - \alpha) * R_{t-1}^{'}
```

Comparison between baseline models

We have chosen our error metric for comparison between models as **MAPE** (**Mean Absolute Percentage Error**) so that we can know that on an average how good is our model with predictions and **MSE** (**Mean Squared Error**) is also used so that we have a clearer understanding as to how well our forecasting model performs with outliers so that we make sure that there is not much of a error margin between our prediction and the actual value

In [47]:

222.35159610215055
```

Plese Note:- The above comparisons are made using Jan 2015 and Jan 2016 only

From the above matrix it is inferred that the best forecasting model for our prediction would be:- $P_{t}^{'} = \alpha * P_{t-1} + (1-\alpha) * P_{t-1}^{'}$ i.e Exponential Moving Averages using 2016 Values

Regression Models

Train-Test Split

Before we start predictions using the tree based regression models we take 3 months of 2016 pickup data and split it such that for every region we have 70% data in train and 30% in test, ordered date-wise for every region

```
In [0]:
```

```
# Preparing data to be split into train and test, The below prepares data in cumulative form which
will be later split into test and train
# number of 10min indices for jan 2015= 24*31*60/10 = 4464
# number of 10min indices for jan 2016 = 24*31*60/10 = 4464
# number of 10min indices for feb 2016 = 24*29*60/10 = 4176
# number of 10min indices for march 2016 = 24*31*60/10 = 4464
# regions_cum: it will contain 40 lists, each list will contain 4464+4176+4464 values which repres
ents the number of pickups
# that are happened for three months in 2016 data
# print(len(regions_cum))
# 40
# print(len(regions cum[0]))
# 12960
# we take number of pickups that are happened in last 5 10min intravels
number of time stamps = 5
# output varaible
# it is list of lists
# it will contain number of pickups 13099 for each cluster
output = []
# tsne lat will contain 13104-5=13099 times lattitude of cluster center for every cluster
# Ex: [[cent lat 13099times],[cent lat 13099times], [cent lat 13099times].... 40 lists]
# it is list of lists
tsne lat = []
# tsne lon will contain 13104-5=13099 times logitude of cluster center for every cluster
# Ex: [[cent long 13099times], [cent long 13099times], [cent long 13099times].... 40 lists]
# it is list of lists
tsne_lon = []
# we will code each day
\# sunday = 0, monday=1, tue = 2, wed=3, thur=4, fri=5,sat=6
 for every cluster we will be adding 13099 values. each value represent to which day of the week
```

Assignment

- Task 1: Incorporate Fourier features as features into Regression models and measure MAPE.
- Task 2: Perform hyper-parameter tuning for Regression models.

```
2a. Linear Regression: Grid Search2b. Random Forest: Random Search2c. Xgboost: Random Search
```

Task 3: Explore more time-series features using Google search/Quora/Stackoverflow to reduce the MAPE to < 12%

Addition of new features to get less MAPE

```

Steps followed during this case study

- 1. The data was analysed for the initial steps and the actual data had to be prepared to apply models on top of that.
- 2. Outliers from the data were detected after proper analysis and some basic domain knowledge and were removed from the data.
- 3. The need was to have certain features to help train the model and so proper featurization was done for time series data and appropriate features were extracted.
- 4. These features are then used for the purpose of modelling.
- 5. Different models have been applied after hyperparameter tuning and the results seen are mentioned above.
- 6. MLP and LSTM are then applied after adding new features to lower the Mean Absolute Percentage Error (Key Metric) upto a value of 5.63% only on the test data.
